Neutrinos in Astrophysics and Cosmology Part II

Neutrinos in Ordinary Stars

Georg G. Raffelt

Max-Planck-Institut für Physik, München, Germany

Equations of Stellar Structure

Assume spherical symmetry and static structure (neglect kinetic energy)
Excludes: Rotation, convection, magnetic fields, supernova-dynamics, ...

Hydrostatic equilibrium

$$\frac{dP}{dr} = -\frac{G_N M_r \rho}{r^2}$$

Energy conservation

$$\frac{dL_r}{dr} = 4\pi r^2 \epsilon \rho$$

Energy transfer

$$L_r = \frac{4\pi r^2}{3\kappa\rho} \frac{d(aT^4)}{dr}$$

r	Radius from center
P	Pressure
G_N	Newton's constant
ρ	Mass density
M_r	Integrated mass up to r
L_r	Luminosity (energy flux)
ϵ	Local rate of energy generation [erg/g/s] $\epsilon = \epsilon_{\text{nuc}} + \epsilon_{\text{grav}} - \epsilon_{\text{v}}$
κ	Opacity $\kappa^{-1} = \kappa_{\gamma}^{-1} + \kappa_{\text{c}}^{-1}$
κ_{γ}	Radiative opacity $\kappa_{\gamma}\rho = \langle \lambda_{\gamma} \rangle_{\text{Rosseland}}^{-1}$
κ_{c}	Electron conduction

Virial Theorem and Hydrostatic Equilibrium

Hydrostatic equilibrium

$$\frac{dP}{dr} = -\frac{G_N M_r \rho}{r^2}$$

Integrate both sides

$$\int_0^R dr 4\pi r^3 P' = -\int_0^R dr 4\pi r^3 \frac{G_N M_r \rho}{r^2}$$

L.h.s. partial integration
with $P = 0$ at surface R

$$-3 \int_0^R dr 4\pi r^2 P = E_{\text{grav}}^{\text{tot}}$$

Classical monatomic gas: $P = \frac{2}{3}U$
(U density of internal energy)

$$U^{\text{tot}} = -\frac{1}{2} E_{\text{grav}}^{\text{tot}}$$

Average energy of single
“atoms” of the gas

$$\langle E_{\text{kin}} \rangle = -\frac{1}{2} \langle E_{\text{grav}} \rangle$$

Virial Theorem

Most important tool to understand
self-gravitating systems

Dark Matter in Galaxy Clusters

Coma Cluster

A gravitationally bound system of many particles obeys the virial theorem

$$2\langle E_{\text{kin}} \rangle = -\langle E_{\text{grav}} \rangle$$

$$2\left\langle \frac{mv^2}{2} \right\rangle = \left\langle \frac{G_N M_r m}{r} \right\rangle$$

$$\langle v^2 \rangle \approx G_N M_r \langle r^{-1} \rangle$$

Velocity dispersion
from Doppler shifts
and geometric size

Total Mass

Dark Matter in Galaxy Clusters

Fritz Zwicky:
Die Rotverschiebung von
Extragalaktischen Nebeln
(The redshift of extragalactic
nebulae)
Helv. Phys. Acta 6 (1933) 110

In order to obtain the observed average Doppler effect of 1000 km/s or more, the average density of the Coma cluster would have to be at least 400 times larger than what is found from observations of the luminous matter.
Should this be confirmed one would find the surprising result that **dark matter** is far more abundant than luminous matter.

Virial Theorem Applied to the Sun

$$\langle E_{\text{kin}} \rangle = -\frac{1}{2} \langle E_{\text{grav}} \rangle$$

Virial Theorem

Approximate Sun as a homogeneous sphere with

Mass $M_{\text{sun}} = 1.99 \times 10^{33} \text{ g}$

Radius $R_{\text{sun}} = 6.96 \times 10^{10} \text{ cm}$

Gravitational potential energy of a proton near center of the sphere

$$\langle E_{\text{grav}} \rangle = -\frac{3}{2} \frac{G_N M_{\text{sun}} m_p}{R_{\text{sun}}} = -3.2 \text{ keV}$$

Thermal velocity distribution

$$\langle E_{\text{kin}} \rangle = \frac{3}{2} k_B T = -\frac{1}{2} \langle E_{\text{grav}} \rangle$$

Estimated temperature

$$T = 1.1 \text{ keV}$$

Central temperature from standard solar models

$$T_c = 1.56 \times 10^7 \text{ K} \\ = 1.34 \text{ keV}$$

Hydrogen burning: Proton-Proton Chains

Hydrogen Burning: CNO Cycle

Thermonuclear Reactions and Gamow Peak

Coulomb repulsion prevents nuclear reactions, except for Gamow tunneling

Tunneling probability

$$p \propto E^{-1/2} e^{-2\pi\eta}$$

With Sommerfeld parameter

$$\eta = \left(\frac{m}{2E} \right)^{1/2} Z_1 Z_2 e^2$$

Parameterize cross section with astrophysical S-factor

$$S(E) = \sigma(E) E e^{2\pi\eta(E)}$$

LUNA Collaboration, nucl-ex/9902004

Main Nuclear Burnings

Hydrogen burning $4p + 2e^- \rightarrow {}^4\text{He} + 2\nu_e$

- Proceeds by pp chains and CNO cycle
- No higher elements are formed because no stable isotope with mass number 8
- Neutrinos from $p \rightarrow n$ conversion
- Typical temperatures: 10^7 K (~1 keV)

Helium burning

“Triple alpha reaction” because ${}^8\text{Be}$ unstable, builds up with concentration $\sim 10^{-9}$

Typical temperatures: 10^8 K (~10 keV)

Carbon burning

Many reactions, for example

Typical temperatures: 10^9 K (~100 keV)

- Each type of burning occurs at a very different T but a broad range of densities
- Never co-exist in same location

Hydrogen Exhaustion

Main-sequence star

Hydrogen Burning

Helium-burning star

ASTROPHYSICAL DETERMINATION OF THE COUPLING CONSTANT FOR THE ELECTRON-NEUTRINO WEAK INTERACTION

Richard B. Stothers*

Goddard Institute for Space Studies, National Aeronautics and Space Administration, New York, New York 10025

(Received 22 December 1969)

The existence of the $(\bar{\nu}_e)(\bar{\nu}_e e)$ weak interaction is confirmed by the results of nine astrophysical tests. The value of the coupling constant is equal to, or close to, the coupling constant of beta decay, namely, $g^2 = 10^{0 \pm 2} g_\beta^2$.

Of all the astrophysical tests applied so far for the inference of a direct electron-neutrino interaction in nature, none has unambiguously provided a useful upper limit on the coupling constant, which in the $V-A$ theory of Feynman and Gell-Mann¹ is taken to be equal to the "universal" weak-interaction coupling constant measured from beta decays (called g_β hereafter). However, it is important to point out that these tests, made by the author and his colleagues during the past eight years, do provide a nonzero lower limit, and therefore establish at least the existence of the $(\bar{\nu}_e)(\bar{\nu}_e e)$ interaction. It should be emphasized, nonetheless, that all of these tests rely on the validity of various stellar model calculations. These models, while not subject to scrutiny in the same sense as a laboratory ex-

relative theoretical lifetimes, calculated with and without the inclusion of neutrino emission. In this Letter, the unmodified term "luminosity" will mean the photon luminosity L radiated by the star. The "neutrino luminosity" will be designated L_ν . Quantities referring to the sun are subscripted with an encircled dot.

The most accurate available data on white dwarfs are those collected by Eggen⁷ for the two clusters Hyades and Pleiades and for the nearby general field. Of chief interest here are the hot white dwarfs, for which the observational data^{7,8} have been reduced following the procedure of Van Horn.⁹ The resulting luminosities are estimated to have a statistical accuracy of ± 0.1 in $\log(L/L_\odot)$, which is adequate here.

Models of cooling white dwarfs have been con-

Self-Regulated Nuclear Burning

Main-Sequence Star

Virial Theorem $\langle E_{\text{kin}} \rangle = -\frac{1}{2} \langle E_{\text{grav}} \rangle$

Small Contraction

- Heating
- Increased nuclear burning
- Increased pressure
- Expansion

Additional energy loss (“cooling”)

- Loss of pressure
- Contraction
- Heating
- Increased nuclear burning

Hydrogen burning at a nearly fixed T

- Gravitational potential nearly fixed:
 $G_N M/R \sim \text{constant}$
- $R \propto M$ (More massive stars bigger)

Degenerate Stars ("White Dwarfs")

Assume T very small
→ No thermal pressure
→ Electron degeneracy is pressure source

Pressure ~ Momentum density x Velocity

- Electron density $n_e = p_F^3 / (3\pi^2)$
- Momentum p_F (Fermi momentum)
- Velocity $v \propto p_F / m_e$
- Pressure $P \propto p_F^5 \propto \rho^{5/3} \propto M^{5/3} R^{-5}$
- Density $\rho \propto M R^{-3}$
(Stellar mass M and radius R)

Hydrostatic equilibrium

$$\frac{dP}{dr} = -\frac{G_N M_r \rho}{r^2}$$

With $dP/dr \sim -P/R$ we have approximately

$$P \propto G_N M \rho R^{-1} \propto G_N M^2 R^{-4}$$

Inverse mass-radius relationship
for degenerate stars: $R \propto M^{-1/3}$

$$R = 10,500 \text{ km} \left(\frac{0.6 M_{\text{sun}}}{M} \right)^{1/3} (2Y_e)^{5/3}$$

(Y_e electrons per nucleon)

For sufficiently large mass,
electrons become relativistic

- Velocity = speed of light
- Pressure

$$P \propto p_F^4 \propto \rho^{4/3} \propto M^{4/3} R^{-4}$$

No stable configuration

Chandrasekhar mass limit

$$M_{\text{Ch}} = 1.457 M_{\text{sun}} (2Y_e)^2$$

Degenerate Stars

Inverse mass-radius relationship
for degenerate stars: $R \propto M^{-1/3}$

Chandrasekhar mass limit
 $M_{\text{Ch}} = 1.457 M_{\text{sun}} (2Y_e)^2$

Stellar Collapse

Stellar Collapse

Onion structure

Collapse (implosion)

Giant Stars

Main-sequence star $1M_{\odot}$
(Hydrogen burning)

$\epsilon_{\text{nuc}}(\text{H})$ relates to
 $T \propto \Phi_{\text{grav}} \propto M/R$
of full star

Helium-burning star $1M_{\odot}$

Large surface area
→ low temperature
→ “red giant”
Large luminosity
→ mass loss

“Envelope”
fully convective

$\epsilon_{\text{nuc}}(\text{He})$ relates to
 $T \propto \Phi_{\text{grav}} \propto M/R$
of core

$\epsilon_{\text{nuc}}(\text{H})$ determined by
 $T \propto \Phi_{\text{grav}}$ of core
→ huge $L(\text{H})$

Evolution of a Low-Mass Star

Limits on Axion-Photon-Coupling

Core-Mass at Helium Ignition

G. Raffelt, Stars as Laboratories
for Fundamental Physics (1996)

Catalan et al.,
astro-ph/9509062

Core mass at helium ignition established to $\pm 0.02 M_{\text{sun}}$ or $\pm 4\%$

Core-Mass Dependence on Neutrino Cooling

Multiply standard neutrino loss rates with a factor F_ν

- Core mass (upper curve)
- Radial coordinate of helium ignition (lower curve)

Change of core mass

Neutrinos from Thermal Plasma Processes

Photo (Compton)

Plasmon decay

Pair annihilation

Bremsstrahlung

Plasmon Decay in Neutrinos

Vacuum:

- Photon massless
- Can not decay into other particles, even if they themselves are massless

Plasmon decay

Vacuum:

- Massless neutrinos do not couple to photons
- May have dipole moments or even “millicharges”

Propagation in a medium:

- Photon acquires a “refractive index”
- In a non-relativistic plasma (e.g. Sun, white dwarfs, core of red giant before helium ignition, ...) behaves like massive particle:

$$\omega^2 - k^2 = \omega_{pl}^2$$

Plasma frequency
(electron density n_e)

$$\omega_{pl}^2 = \frac{4\pi\alpha n_e}{m_e}$$

- Degenerate helium core $\omega_{pl} = 18 \text{ keV}$
($\rho = 10^6 \text{ g cm}^{-3}$, $T = 8.6 \text{ keV}$)

In a medium:

- Neutrinos interact coherently with the charged particles which themselves couple to photons
- Induces an “effective charge”
- In a degenerate plasma (electron Fermi energy E_F and Fermi momentum p_F)
$$\frac{e_\nu}{e} = 16\sqrt{2} C_V G_F E_F p_F$$
- Degenerate helium core (and $C_V = 1$)
$$e_\nu = 6 \times 10^{-11} e$$

Neutrino Dipole Moments

Effective coupling of electromagnetic field to a neutral fermion

$$\mathcal{L}_{\text{eff}} = -F_1 \bar{\Psi} \gamma_\mu \Psi A^\mu$$

$$-G_1 \bar{\Psi} \gamma_\mu \gamma_5 \Psi \partial_\nu F^{\mu\nu}$$

$$-\frac{1}{2} F_2 \bar{\Psi} \sigma_{\mu\nu} \Psi F^{\mu\nu}$$

$$-\frac{1}{2} G_2 \bar{\Psi} \sigma_{\mu\nu} \gamma_5 \Psi F^{\mu\nu}$$

Charge $e_\nu = F_1(0) = 0$

Anapole moment $G_1(0)$

Magnetic dipole moment $\mu = F_2(0)$

Electric dipole moment $\varepsilon = G_2(0)$

- Charge form factor $F_1(q^2)$ and anapole $G_1(q^2)$ are short-range interactions if charge $F_1(0) = 0$
- Connect states of equal chirality
- In standard model they represent radiative corrections to weak interaction

- **Dipole moments connect states of opposite chirality**
- Violation of individual flavor lepton numbers (neutrino mixing)
 - Magnetic or electric dipole moments can connect different flavors or different mass eigenstates ("**Transition moments**")
- Usually measured in "Bohr magnetons" $\mu_B = e/(2m_e)$

Plasmon Decay And Stellar Energy Loss Rates

Assume photon dispersion relation like a massive particle (nonrelativistic plasma)

$$E_\gamma^2 - p_\gamma^2 = \omega_{pl}^2 = \frac{4\pi\alpha n_e}{m_e}$$

Decay rate of photon (transverse plasmon) with energy E_γ

$$\Gamma(\gamma \rightarrow \nu\bar{\nu}) = \frac{4\pi}{3} \frac{1}{E_\gamma} \times \begin{cases} \alpha_\nu \left(\omega_{pl}^2 / 4\pi \right) & \text{Millicharge} \\ \frac{\mu_\nu^2}{2} \left(\omega_{pl}^2 / 4\pi \right)^2 & \text{Dipole moment} \\ \frac{C_V^2 G_F^2}{\alpha} \left(\omega_{pl}^2 / 4\pi \right)^3 & \text{Standard model} \end{cases}$$

Energy-loss rate of stellar plasma (temperature T and plasma frequency ω_{pl})

$$Q(\gamma \rightarrow \nu\bar{\nu}) = \int \frac{2d^3\vec{p}}{(2\pi)^3} \frac{E_\gamma \Gamma}{e^{E_\gamma/T} - 1} = \frac{8\zeta_3}{3\pi} T^3 \times \begin{cases} \alpha_\nu \left(\omega_{pl}^2 / 4\pi \right) \\ \frac{\mu_\nu^2}{2} \left(\omega_{pl}^2 / 4\pi \right)^2 \\ \frac{C_V^2 G_F^2}{\alpha} \left(\omega_{pl}^2 / 4\pi \right)^3 \end{cases}$$

Globular Cluster Limits on Neutrino Dipole Moments

Compare magnetic-dipole plasma emission with standard case

$$\frac{Q_\mu}{Q_{SM}} = \frac{2\pi\alpha\mu_\nu^2}{c_V^2 G_F^2 \omega_{pl}^2}$$

For red-giant core before helium ignition $\omega_{pl} = 18$ keV

$$\frac{Q_\mu}{Q_{SM}} = 9 \times 10^{22} \left(\frac{\mu_\nu}{\mu_B} \right)^2$$

Require this to be < 1

$$\mu_\nu < 3 \times 10^{-12} \mu_B$$

Globular-cluster limit on neutrino dipole moment

$$\mu_\nu < 2 \times 10^{-12} \mu_B$$

Standard Dipole Moments for Massive Neutrinos

In standard electroweak model,
neutrino dipole and
transition moments
are induced at higher order

Massive neutrinos ν_i ($i = 1, 2, 3$),
mixed to form weak eigenstates

$$\nu_\ell = \sum_{i=1}^3 U_{\ell i} \nu_i$$

Explicit evaluation for Dirac
neutrinos
(Magnetic moments μ_{ij}
electric moments ε_{ij})

$$\mu_{ij} = \frac{e\sqrt{2}G_F}{(4\pi)^2} (m_i + m_j) \sum_{\ell=e,\mu,\tau} U_{\ell j} U_{\ell i}^* f\left(\frac{m_\ell}{m_W}\right)$$

$$\varepsilon_{ij} = \dots (m_i - m_j) \dots$$

$$f\left(\frac{m_\ell}{m_W}\right) = -\frac{3}{2} + \frac{3}{4}\left(\frac{m_\ell}{m_W}\right)^2 + O\left(\left(\frac{m_\ell}{m_W}\right)^4\right)$$

Standard Dipole Moments for Massive Neutrinos

Diagonal case
(Magnetic moments
of Dirac neutrinos)

$$\mu_{ii} = \frac{3e\sqrt{2}G_F}{(4\pi)^2} m_i = 3.20 \times 10^{-19} \mu_B \frac{m_i}{\text{eV}} \quad \mu_B = \frac{e}{2m_e}$$

$$\epsilon_{ij} = 0$$

Off-diagonal case
(Transition moments)

First term in
 $f(m_\lambda/m_W)$ does not
contribute
("GIM cancellation")

$$\mu_{ij} = \frac{3e\sqrt{2}G_F}{4(4\pi)^2} (m_i + m_j) \left(\frac{m_\tau}{m_W} \right)^2 \sum_{\ell=e,\mu,\tau} U_{\ell j} U_{\ell i}^* \left(\frac{m_\ell}{m_\tau} \right)^2$$

$$= 3.96 \times 10^{-23} \mu_B \frac{m_i + m_j}{\text{eV}} \sum_{\ell=e,\mu,\tau} U_{\ell j} U_{\ell i}^* \left(\frac{m_\ell}{m_\tau} \right)^2$$

$$\epsilon_{ij} = \dots (m_i - m_j) \dots$$

Largest neutrino mass eigenstate $0.05 \text{ eV} < m < 0.7 \text{ eV}$

For Dirac neutrino expect

$$1.6 \times 10^{-20} \mu_B < \mu_\nu < 2.2 \times 10^{-19} \mu_B$$

Consequences of Neutrino Dipole Moments

Spin
precession
in external
E or B fields

$$i \frac{\partial}{\partial t} \begin{pmatrix} \nu_L \\ \nu_R \end{pmatrix} = \begin{pmatrix} 0 & \mu_\nu B_T \\ \mu_\nu B_T & 0 \end{pmatrix} \begin{pmatrix} \nu_L \\ \nu_R \end{pmatrix}$$

Scattering

$$\frac{d\sigma}{dT} = \frac{G_F^2 m_e}{2\pi} \left[(C_V + C_A)^2 + (C_V - C_A)^2 \left(1 - \frac{T}{E_\nu}\right)^2 + (C_V^2 - C_A^2) \frac{m_e T}{E_\nu^2} \right] + \alpha \mu_\nu^2 \left[\frac{1}{T} - \frac{1}{E_\nu} \right]$$

T electron recoil energy

Plasmon
decay in
stars

$$\Gamma = \frac{\mu_\nu^2}{24\pi} \omega_{pl}^3$$

Decay or
Cherenkov
effect

$$\Gamma = \frac{\mu_\nu^2}{8\pi} \left(\frac{m_2^2 - m_1^2}{m_2} \right)^3$$

Neutrino Radiative Lifetime Limits

$$\Gamma_{\nu \rightarrow \nu' \gamma} = \frac{\mu_{\text{eff}}^2}{8\pi} m_\nu^3$$

$$\Gamma_{\gamma \rightarrow \nu \bar{\nu}} = \frac{\mu_{\text{eff}}^2}{24\pi} \omega_{\text{pl}}^3$$

For low-mass neutrinos, plasmon decay in globular cluster stars yields most restrictive limits

Astrophysical Magnetic Fields

Field strength and length scale where neutrinos with specified dipole moment would suffer complete depolarization

"Hillas Plot"
[ARAA 22, 425
(1984)]
